DESCRIPTORS- *LARGE GROUP INSTRUCTION, *INDIVIDUAL DIFFERENCES, *INSTRUCTIONAL TECHNOLOGY, *MUSIC EDUCATION, *AUTOINSTRUCTIONAL METHODS, METHODS RESEARCH, MUSIC, MUSIC THEORY, MUSIC TECHNIQUES, PREDICTIVE ABILITY (TESTING), EDUCATIONAL RESEARCH, AUTOINSTRUCTIONAL LABORATORIES, LEARNING LABORATORIES,

THERE IS A DICHOTOMY WHICH EXISTS IN EDUCATION AND--IN PARTICULAR, IN THE DOMAIN OF MUSIC LEARNING--IN THE ASSUMPTION THAT INDIVIDUAL DIFFERENCES IN LEARNING ARE MET IN A LARGE GROUP-INSTRUCTION PROGRAM. THE MAIN OBJECTIVE IN THE RESEARCH WAS TO TEST AND TO EVALUATE A CLINICAL TYPE OF INSTRUCTIONAL PROGRAM BASED ON INDIVIDUAL DIFFERENCES IN SUCH A MANNER THAT DIAGNOSES COULD BE MADE AND INDIVIDUAL'S MUSIC AILMENTS COULD BE TREATED IN LEARNING THREE BASIC MUSIC ELEMENTS. PHASE I WAS AN ITEM ANALYSIS OF STUDENT WORKSHEETS AND TEST PAPERS ACCUMULATED FROM USING AUTO-INSTRUCTIONAL METHODS IN PAST RESEARCH. PHASE II WAS A DISCRIMINATIVE ANALYSIS SO THAT PREDICTIONS COULD BE MADE FOR THE SELECTIVE AUTO-INSTRUCTIONAL TREATMENT OF INDIVIDUALS. PHASE III WAS AN EXPERIMENT USING THOSE FRESHMEN MUSIC STUDENTS WHO WERE ENROLLED IN THE FUNDAMENTALS OF MUSIC COURSE AT THE OHIO STATE UNIVERSITY IN THE ACADEMIC YEAR 1966-67. FROM THE RESEARCH IT WAS POSSIBLE TO DISTINGUISH INDIVIDUALS AND GROUPS AS A PARTICULAR TYPE OF LEARNING PROBLEM, WHICH COULD BE DEALT WITH ON AN INDIVIDUAL-GROUP BASIS, WITH THE PREDICTED GAIN SCORES ESTABLISHED. INTRODUCTION

Historically, educational and psychological research studies investigating classroom instruction have been oriented toward group research. There has been a tradition of group research established which includes such variables as class size and homogeneous groupings. New research has been directed toward the development of new taxonimies of learning as well as new technologies in the field of education. Similarly, testing programs have been designed to measure certain learned skills, capacity for learning, and/or acquired knowledge of the individual. These testing data when reported emphasize group characteristics. Instruction and techniques involving various media have been researched and evaluated, the data reported either show no significant difference or show the gains for group learning achieved by new procedures to be higher than achievements made by students in a traditional classroom approach. Group presentations of these new approaches have been standardized, and despite a reported significant improvement or no significant difference in learning, the variance reported in the learning among students would be expected to be as great as the variance in learning which exists in the traditional classroom.

Individual differences exist as a large source of variance in reported data. To date, there seems to be no research which has found a single method that is universally successful and meets the needs of individual differences. A contextual research program at The Ohio State University for the past three years has investigated the differential effects of twenty-seven auto-instructional methods. During this time the accumulated data and experiences of students observed indicate a next step in research was needed to meet the challenge of learning. The next step was to use existing data and researched auto-instructional methods in a different manner. Even though the researched auto-instructional methods have improved learning, there was no evidence to support the position of a single best method. There was evidence to suggest the possibility that measurable individual differences were important in <u>the learning</u> or <u>not learning</u> of an individual by a particular method. It appeared, therefore, that a new kind of strategy was needed to attack the problem of improved learning for all. Individual differences which could be measured could be utilized. Educational ills must be individually diagnosed. A spectrum of relevant research-proven differential treatments must be available.

Even though much has been said about meeting individual differences in education, little attempt has been made to use measurable individual differences to provide tailored instructional programs to meet the individual needs.

There is a need to develop a diagnostic testing and instructional program which incorporates differential treatments that are geared to the individual differences of students and will give these students a predicted assurance of optimal learning. Since present teachers have neither these kinds of data or instruments, the testing-instructional programs must be ones which can be codified and are economically and generally feasible.

RELATED RESEARCH

Although there has been considerable research undertaken to explore human learning, there is little evidence in the research literature that any attempts have been made to pair individual differences to achievement in learning except after the fact. The recognition of individual differences has been reported when these differences exist only as a source of variance in a statistical analysis of research data. To date no teaching machine and/or program for learning appears to be adequate for meeting the needs of all students (Coulson and Silberman, 1961), (Campbell, 1963). There is some indication (Krumboltz, 1964) that even the difference in effective learning brought about with a verbal program in which some students made a required response and other students were not required to make a response might be due to individual differences.

For ten years, an organized program of research in music learning has been in progress at The Ohio State University. Spohn (1959) reported an experiment in music learning in which a self-presentation technique was used. Information was presented aurally on magnetic tape and students wrote their responses. When the experimental group's achievement was compared with the achievement of a control group using traditional instruction, the experiment group showed a significant improvement in their learning of the material. A refinement of this technique, based on a paired-associate procedure, was reported (Spohn, 1962) using different subject matter for learning. Again the data showed significant improvement in the groups' learning.

In both studies, however, even though all students made improvement some students did not achieve optimal learning. In an attempt to research this problem further, the learning of three basic music elements using four different methods was investigated (cf. Film made pursuant to a contract with the U. S. Office of Education, "Self-Teaching of Music Fundamentals", The Ohio State University MCMLXIV, Charles L. Spohn). Spohn and Poland (1964) reported the differential effects of aural or visual presentation of learning basic music materials when students used either written or voice responses. Spohn (1965) reported that the students, even though trained differently, showed a great amount of transfer to like tasks. In each of the experiments the kind of response which students made was statistically significant to their learning; however, the manner in which information was presented was not significant. An additional finding (Spohn and Poland, 1964) was that the background factors which included various aspects of specific music training, as well as general education, have significant influences upon the students' learned behavior. The individual differences (other factors) were significant in each experiment.

A further extension of this research was continued (Spohn, 1965c). The first phase of the research investigated the differential effects of six additional auto-instructional methods for learning each of three basic music elements. Spohn (1964) reported group gains from one of these experiments. The data indicated one method out of six is superior for learning a basic music element by some students, while not as effective for others. On the other hand, group gains in all instances improved. Once again, however, it is observed that individual differences (other factors) did, in fact affect individual outcomes. The data from the continued research (Spohn, 1965c) gave further support to the earlier findings.

An extensive testing program has been developed and used over a period of ten years (Poland, 1960) for the selective admission of students to the music curricula at The Ohio State University. Some of the refinements and use of this testing program for the research program at The Ohio State University are reported in An Evaluation of Two Methods Using Magnetic Tape Recordings for Programed Instruction in the Elemental Materials of Music (Spohn and Poland, 1964, pp. 27-37). The test data to date have been used primarily as an instrument for the selective admission of students into the music curricula. In addition, it has been a routine procedure to use these tests in all relevant investigations because their use forms a common statistical reference base.

OBJECTIVES

The main objective in the research was to test and evaluate a clinical type of instructional program for diagnosing and treating individual basic music ailments. This main objective can be broken down into three specific objectives:

1.- to determine from a further analysis of data from past research sponsored by the U. S. Office of Education (which evaluated only differential effects of twenty-seven auto-instructional methods) individual student error patterns and work scores and classify these by method and individual characteristics;

2.- to establish a system for diagnosing students' basic music learning ailments and predicted from an existing spectrum of differential auto-instructional methods the needed treatment for a given set of individual characteristics;

3.- to undertake an experiment with a group of students so that an evaluation of this clinical type of instructional program can be made.

METHOD

There has been a large quantity of data accumulated from both the testing program and the auto-instructional research program which goes beyond the original intent of either. It was believed, therefore, that the test data[1] and the data from the immediate past three years' auto-instructional research program in music[2] could be used to provide the basis for the selective educational treatment of individuals to learn music.

---

[1]Background information and test data include: American College Test, Music Skill and Information, General Music Information, Music Recognition, Basic Elements of Music Test, Pretest and Posttest for Basic Music Skills, Age, Sex, Applied Music Performance Area, and Applied Music Audition Grade (cf. Spohn and Poland, 1964, p. 36; and Spohn 1963c, pp. 24, 69 and 104).

[2]Student worksheets and tests from OE Grant Number 7-34-0430-172, An Evaluation of Two Methods Using Magnetic Tape Recordings for Programed Instruction in the Elemental Materials of Music and OE Grant Number 7-45-0430-214, A Comparison Between Different Stimuli Combined with Two Methods for Providing Knowlege of Results in Music Instruction.

Procedure. The work plan for the research was carried out in three phases.

Phase I

1.- Phase I was an item analysis of student worksheets and test papers accumulated from past research[3], which investigated the differential effects in learning three basic music elements by using nine auto-instructional methods (cf. Figure 1). This is a total of twenty-seven methods.

Figure 1

Basic Music Element	Music Auto-Instructional Treatment								
	1	2	3	4	5	6	7	8	9
A Rhythm									
B Interval									
C Tone Group									

2.- Code and develop a scoring procedure from the item analysis which will result in a total workscore for each student which could be used in an existing statistical program and could be used in the prediction portion of this study.

---

[3]Approximately 450 students had been through the instructional program. These data were a large source of information. Item analyses (even though considered raw data) of these kinds of materials provide information about individual errors and learning patterns that were not available through more sophisticated statistical analyses. However, even coding and scoring did not make their use in statistical analysis possible.

Phase II

1. Phase II was a discrimination analysis, using data from the past three years' research (cf. footnote number 1) and work-scores from the item analysis, step 2, Phase I, to predict and thereby to provide for the selective educational auto-instructional treatment of individuals to learn three basic music elements by means of the existing spectrum of auto-instructional methods shown in Figure 1. In Figure 2, it is possible to observe the various relationships between the categorization of individual characteristics, basic music elements, and auto-instructional treatments. An illustration of this procedure might be as follows (cf. Figure 2):

Figure 2

	Classification of Individual Characteristics								
	1	2	3	4	5	6	7	8	9
Basic Music Elements	AUTO-INSTRUCTIONAL TREATMENTS								
	I	II	III	IV	V	VI	VII	VIII	IX
A Rhythm									
B Interval									
C Tone Group									

A general individual characteristic classification might be one in which those girls who have had private piano instruction (cell 1) show the most improvement in learning the basic music element, rhythm (cell A) using auto-instructional method I, which incorporates an aural presentation-written-response and visual knowledge of results. This provides the basis for Phase III.

Phase III

Phase III was a three-part experiment. The sample used in this study consisted of those Freshmen who were enrolled in the fundamentals of music course at The Ohio State University in the academic year 1966-67 (approximately 130 students).

These students, upon entry to the fundamentals of music class in the autumn of 1966, were given tests[3] (Spohn and Poland, 1964) referred to in Phase II, number 1.

On the basis of the data obtained from Phases I, II, and the test data, Phase III, students' music educational malady was diagnosed and these students were assigned the appropriate predicted auto-instructional treatment(s) to achieve optimum learning, Figure 2. It should be noted, however, that the possibility existed that all cells shown in Figure 2 would not be used. This, of course, depended upon the outcome of the analyses. (cf. Film made pursuant to a contract with the U.S. Office of Education, "Self-Teaching of Music Fundamentals", The Ohio State University MCMLXIV, Charles L. Spohn, for an example of some of the auto-instructional methods.)

RESULTS AND FINDINGS

In each of three quarters, a group of approximately 130 students was divided into three groups, each of which was given a particular type of music training (cf. Appendix B). In each quarter each student was tested on the three aspects of the training, even though he was subjected to only one of them. Both the training groups and the tests are designated A, B, C. In summary:

Groups or tests	Autumn-Rhythm	Winter-Intervals	Spring-Tone Groups
A	Single tone	Ascending	Ascending
B	Series	Descending	Descending
C	Taps	Harmonic	Ascending/Descending

At the beginning of each quarter, all students took the three tests A, B, C. These will be referred to as the initial tests or pretests. On the basis of these initial tests, the students were divided into three groups A, B, C. An attempt was made to balance the high, medium, and low initial scores in the three groups. In the Winter and Spring Quarter the additional criterion of splitting up the groups from the previous quarter was also invoked. It is believed that the resulting groups were as balanced on initial scores as possible.

Three tests A, B, C, were administered to all the students at the end of each quarter. The difference between the posttest and the pretest will be called the gain score. In the Autumn Quarter the maximum possible score on a test was 100. The percentage gain score in this case would be (Gain Score)/(100 - Pre-Score). For the Winter and Spring Quarters the maximum scores were 64 and 36. For those quarters the percentage gain scores were Gain/(64-pre) and Gain/(36-pre), respectively.

Tables I-V give the means, standard deviations and correlations for the Initial Scores, the Gain Scores and the Percentage Gain Scores. Note that for Autumn the scores are also divided into Duple, Tripe and Duple-Triple combined.

Preliminary Analysis

The first question to be raised regards the relevancy of the music scores, MSI, GI, MR. To answer this an analysis of variance on the groups A, B, C, with the pre (or initial) score and the scores MSI, GI, MR in covariance was carried out. This was done on the Duple A, B, C, A+B+C and Triple A, B, C, A+B+C gain scores for the Autumn Quarter. Some of these results are summarized in Table VI The first F in the table tests the hypothesis that the coefficient of the pre score was always significantly different than zero. The F's (with one exception) for the variables MSI, GI, MR were generally small. It was decided at this point to ignore these measurements in subsequent analyses.

The average effect of a particular type of training, i.e., groups A, B, C on students in the Autumn Quarter on students' training in the Winter Quarter was minimized by distributing the students, say, in the Autumn A group over all three groups in the Winter Quarter. The same was done in the Spring Quarter relative to the groups in the Winter Quarter. An analysis of variance was carried out to see whether the preceding group division was important. In particular, a given student could be classified Autumn A, B, C, and Winter A, B, C and the effects of these classifications as well as their interaction was studied. Table VI contains the F's that test whether the effects of these classifications are zero on the gain scores A, B, C and A+B+C. This analysis was carried out for both Winter-Autumn and Spring-Winter. Only students that were present both quarters were used. In all cases the interaction of the two quarter classifications was not significant as well as the effect of the previous quarter classification. This result justifies -- to some extent at least -- analyzing the scores for each quarter separately.

Comparison of Group Means

Since the three tests A, B, C are correlated, the hypothesis of no differences in the training groups was tested in a multi-variate analysis of variance. For each quarter the following array exhibits the means:

Table VI

Results of Preliminary Analysis

F's for testing hypotheses that certain given variables have no effect in the regression of the gain scores on these variables.

Autumn Quarter (n = 128)

	Gain Score	Group A,B,C	MSI,GI,Mr
Duple	A	1.31	3.05*
	B	.30	1.34
	C	.50	2.05
	A+B+C	.21	1.54
Triple	A	1.85	.45
	B	1.22	.96
	C	.24	.76
	A+B+C	.03	.49

Winter Quarter (n = 106)

Gain Score	Autumn Group A,B,C	Winter Group A,B,C	Autumn and Winter Group Interaction
A	2.47	14.08**	1.20
B	1.01	2.18	.64
C	2.21	.70	1.16
A+B+C	2.00	1.93	1.32

Spring Quarter (n = 97)

Gain Score	Winter Group A,B,C	Spring Group A,B,C	Winter and Spring Group Interaction
A	2.00	3.48*	0.26
B	1.49	3.92*	1.53
C	.60	2.31	.36
A+B+C	2.46	.24	.63

Test	Group A	Group B	Group C
A	m_{AA}	m_{AB}	m_{AC}
B	m_{BA}	m_{BB}	m_{BC}
C	m_{CA}	m_{CB}	m_{CC}

The null hypothesis to be tested is that simultaneously

$$m_{AA} = m_{AB} = m_{AC}$$

$$m_{BA} = m_{BB} = m_{BC}$$

$$m_{CA} = m_{CB} = m_{CC}$$

For a given group the three test scores give rise to a variance-covariance matrix. As an example, refer to Table VII, Autumn, first page, the first entry 363.2590 is the sample variance for group A on the gain A score. The square root of this number is 19.059, the standard deviation found in Table I. Similarly, 397.1458, 400.6736 are the variances of the gain B and gain C scores in group A. The 338.64 is the covariance of the gain A and gain B score. The correlation of A and B could be obtained by dividing the covariance by the two associated standard deviations. Briefly, the variance-covariance matrix for a group contains information about the variability of the scores and their interdependence. Tables VII-IX contain these matrices (the lower half was not typed for convenience) for each group and for the entire group for both the gain scores and percentage gain scores. One should note that in the separate groups the variances and covariances are computed about their respective means whereas in the entire group the variances and covariances are computed about the means of the entire group. Intuitively, then, if the null hypothesis is correct, one would expect that the average (Table X) of the three group matrices would resemble the matrix for the entire group.

The likelihood ratio test of the hypothesis is based on this idea and is, indeed, determined by the ratio of the determinants of these matrices. These D_c/D_a ratios are tabulated in Table XI The exact distribution of this ratio is known and the probability associated with this ratio is also given in Table XI. In all cases the hypothesis may be rejected, i.e., differences exist among the groups on the gain scores and on the percentage gain scores.

Since Test A is over the training received in group A, Test B over that in group B, Test C over that in group C, one might expect that the means m_{AA}, m_{BB}, m_{CC} would be the largest in their respective comparisons. Except for Test C in the Autumn Quarter this was the case. This fact combined with the above test of significance would lead to the conclusion that the training was at least effective in raising the score in that particular area.

The use of the percentage gain score allows one to compare the A, B, C scores within a group. No test of significance was carried out here but one can observe that in the A group the percentage gain for the A score was the largest, in the B group the percentage gain for the B score was the largest, but that there was no consistency for the C group.

Analysis of Gain Scores as Related to Groups and Initial Scores

For each of the gain scores the effects of the classifications by groups was studied in an analysis of variance with the three initial scores in covariance. The results are given in Table We shall look at the first one as an example. The gain in A (duple + triple) is given in a multiple regression form by

$$\text{gain in A} = -1.200\ (\text{pre A}) + 0.1051\ (\text{pre B}) + 0.579\ (\text{pre C})$$

$$+ \begin{cases} 2.402 & \text{if in group A} \\ -2.252 & \text{if in group B} \\ -0.150 & \text{if in group C} \end{cases} + 53.263$$

Thus, the gain in A is greatest if the pre A score is small, the pre B, pre C scores large and one is in group A. The coefficients of the pre A and pre C scores are significantly different than zero.

Table XI

Testing Equality of Means

Quarter	Variable	D_c/D_a	Probability
Autumn	Gain-Duple	.9571	.473
	Gain-Triple	.8783	.0111
	Gain-Duple + Triple	.8906	.022
	% Gain-Duple	.9258	.134
	% Gain-Triple	.9158	.083
	% Gain-Duple + Triple	.8704	.007
Winter	Gain	.8271	.002
	% Gain	.7937	.0003
Spring	Gain	.8266	.005
	% Gain	.8755	.045
	Selected Group		
Autumn	Gain Duple	.9139	.076
	Gain Triple	.9174	.090
	Gain Duple + Triple	.8664	.021
	% Gain Duple	.8033	.0001
	% Gain Triple	.8991	.035
	% Gain Duple + Triple	.7860	.0003
Winter	Gain	.7838	.003
	% Gain	.6746	.00001
Spring	Gain	.8636	.084
	% Gain	.8722	.109

In the Winter and Spring Quarters the regressions are rather consistent in that the gain in a score is greatest if the same pre score is least and if the training corresponding to that score is used. A few cases counter to that occur in the Autumn. Furthermore, the groups exhibit more significant differences in the Winter and Spring as opposed to the Autumn. The use of these regression equations as predictors will be examined, as follows.

Prediction of Gain Scores from Initial Scores and Training.

The regression equations given in Tables XII-XIV enable one to predict the mean gain score or the mean percentage gain score for an individual with known pre scores and group assignment. It must be borne in mind that the leeway (or error) involved in such a prediction is determined in great part by the standard deviation. This value is given under σ in Tables XII-XIV and it is immediately evident that the prediction of an individual's score is not very accurate. It is better to think of the prediction of the mean of a group of students rather than of an individual student.

Using the mean pre scores from Table I we shall label an individual as average (A) if his pre score is the average of the total group; we shall label him as low (L) if his pre score is one standard deviation below the mean and as high (H) if his pre score is one standard deviation above the mean. For example, in the Autumn on score A a student is A, L, or H if his initial test is 25.588, 5.621, or 45.555. Using this classification on each initial test, i.e., A, B, C we obtain 27 different "types" of individuals. For each of these types, the predicted mean for each of the three scores is given in Tables XV-XX. This has been done for each quarter and for both gain and percentage gain scores. These tables show the effects of the pre scores, effects which can also be seen directly from the regression coefficients in Tables XII-XIV. The changes from group to group are also evident from Tables XII-XIV.

The Difference between the Post and Pre Scores

The difference between the post and pre scores is the basic measurement in assessing differences among the treatment groups. The analysis of these gain scores is made more precise by taking out the effects due to initial scores in the analysis of covariance. In

an effort to reduce the variability, the percentage gain score was introduced and in Parts II and III both the gain and percentage gain scores have been investigated. This section describes another attempt at forcing more homogeneity in the subjects.

Some of the subjects score quite high on the pretests. This fact insures that their gains are necessarily low and the use of percentage gain helps somewhat but does not seem to take care of these cases too well. In a rather arbitrary manner subjects were deleted if any one of their initial scores was more than one standard deviation above the mean. The resulting group is called the selected group. In the Autumn, the reduction was from 131 to 108, in Winter from 112 to 85, and in Spring from 101 to 80.

The means and standard deviation for the selected group are in Tables XXI-XXV. Tables XXVI, XXVII-XVIIIcontain the Variance-Covariance matrices that are pertinent to the analysis described in Part II. Tables XXX-XXXII contain the regression coefficient similar to Tables XII-XIV.

This analysis did not reveal any differences that were not evident without the group selection, although the gain scores were increased by selection, the variance or standard deviation was not changed appreciably. The percentage gain scores were reduced but so was the variance, so, again, not much was gained by selection. The analysis in Part II and summarized in Table XI shows very little difference between the total group and the selected group. A similar statement applies to the significant regression coefficients in Tables XI-XIV and XXX-XXXII.

DISCUSSION AND SUMMARY

The research undertaken was to determine from further analysis of past research, individual student error patterns, in order to develop work scores and classify these by method and individual characteristics. A further objective of the research was, if possible, to establish a system for diagnosing students' basic music learning ailments and predict from an existing spectrum of differential auto-instructional methods the needed treatment for a given set of individual characteristics. Finally, the research was an experiment with a group of students so that an evaluation of this clinical type instructional program could be made.

A coding system was evolved to undertake the item analysis and subsequent use of individual student error patterns and work scores. The variance in error patterns was not as great as first believed. Even though item analyses of student work offers considerable information, there was no way in which the data could be used to assist in pairing information of student work with different methods of instruction.

A surprising outcome of the initial attempt to diagnose student characteristics from standard test scores used in the School of Music was the lack of relationship of individual characteristics to the training. This is especially noteworthy since analyses of previous research had indicated usable relationships. The lack of relationship of background test scores indicates that such measurements are not critical to the specific learning tasks. It was, therefore, decided to ignore those measurements in placement and subsequent analysis. Instead, a more effective means of placing students in the individual training was on the basis of known pre scores on the training to be undertaken. Even though the data indicate that it is not extremely accurate to predict an individual score on this basis, it is important to note that there are types of individuals who as a group respond to particular types of treatment.

From the research it was possible to distinguish individuals and groups as a particular type of learning problem, which could be dealt with on an individual-group basis. with the predicted gain scores established.

It is evident, from this research, that there is a need to pursue the individuality of students to determine their needs for specialized grouping and treatment for better learning. It appears important to pursue learning problems more from an operational procedure rather than from a background analytical analysis. It appears that what a student is when combined with an appropriate learning environment and motivation is more important than what the student was before a particular learning task was begun. There certainly are a variety of ways in which this problem can be investigated. This research, even though highly controlled, could be classified as a very small step toward larger, more sophisticated research involving computerized instruction, individual counselling and more refined methodology.

It is indeed important to realize, and this research further points out the realization, that individuals must receive specialized attention and instruction to attain the greatest benefit from an instructional or learning environment. It cannot be assumed that every individual receives the same benefit from the same instruction. The elements of individual variability and motivation make even a highly organized instructional environment different for different people. The need is to provide as much flexibility in the system utilizing modern technology and new media in order to enhance the multiple presentations of information to a variety of individuals. The teacher and student should be aware of as many possibilities as are available to meet the challenge of improved learning.

APPENDIX A

THE ANALYSIS OF THE DIFFERENTIAL EFFECTS OF SIX EXPERIMENTAL TREATMENTS FOR THREE BASIC MUSIC ELEMENTS INVESTIGATED IN THE FIRST PHASE OF A GRANT SUPPORTED BY THE U.S. DEPARTMENT OF HEALTH, EDUCATION AND WELFARE, OFFICE OF EDUCATION UNDER TITLE VII 85-864 GRANT NUMBER 7-45-0430-214, A COMPARISON BETWEEN DIFFERENT STIMULI COMBINED WITH TWO METHODS FOR PROVIDING KNOWLEDGE OF RESULTS IN MUSIC INSTRUCTION

SUPPORTING DATA FROM PHASE I, OFFICE OF EDUCATION GRANT NUMBER 7-45-0430-214 WHICH RELATES TO THIS RESEARCH

In Tables I, II, and III the following can be observed:

(1) part number 1 in each Table, there was a significant improvement in the scores of all of the subjects. These pretest and posttest mean scores are shown in number 6;

(2) part number 2, other factors (individuals differences) were significant at the 1 per cent level;

(3) part number 3 and part number 7, there were significant differential effects for the experimental groups of the various auto-instructional music methods.

It is important to know, however, that if all students would have achieved optimal learning the posttest means under number 7 would read:

Table I 182

APPENDIX B

ITEM ANALYSIS CODE AND PROCEDURES

For each type of training, it was desirable to know the most common sources of error and the most common erroneous responses. Therefore, the first exercise attempted by each student for each level of difficulty was examined in order that errors might be tabulated.

Rhythm Item Analysis Code

For analysis of rhythm errors, a code was devised by which numbers were assigned for: (1) each one-beat rhythmic pattern; (2) to indicate that no answer was attempted, and (3) to indicate a "nonsense" response (a nonsense response was designated as one other than the rhythms used).

Duple Rhythm Code

1 =

2 =

3 =

4 =

5 = 
6 =

7 =

8 =

9 = no response

10 = nonsense

Triple Rhythm Code

5 =

6 =

9 = no response

10 = nonsense

RHYTHM - ITEM ANALYSIS

STUDENT NUMBER_____ CLASS_____ Tapes: 20, 40, 60, 80, 100

NAME_____ MODE OF TRAINING_____ YEAR_____

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
111	121	131	141	151	161	211	311	411	511	611	221	331	441	551	661
20 40						40					80				
80 60	60					60									

20 (24)	40 (24)	60 (22)	80 (24)	100 (20)

17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36
231	241	251	261	321	341	351	361	421	431	451	461	521	531	541	561	621	631	641	651

Item analysis sheets were used in which a vertical column was provided for each 3-beat rhythm; and a horizontal space was provided for each appearance of this rhythm in each exercise. For each student response there was an appropriate space in which to code the student's response. The information was further compiled with one master analysis sheet.

Interval Item Analysis Code

Interval item analysis sheets were prepared on which could be recorded, for each student, how often an interval had been incorrectly identified in each exercise in which it appeared. The following code was used:

Interval Code	Interval Code
Perfect Prime - PP	Perfect fifth - P5
Minor second - -2	Minor sixth - -6
Major second - +2	Major sixth - +6
Minor third - -3	Minor seventh - -7
Major third - +3	Major seventh - +7
Perfect fourth - P4	Perfect octave - P*
Tritone - T	

Tone Group Item Analysis Code

Each tone group involves two intervals and one of four rhythm patterns. It was possible to use the same code number for each rhythm previously used during the rhythm portion of the study.

No Response = 9

Nonsense = 0

The same interval abbreviations were employed as shown in the interval study. Item analysis sheets were prepared in which a vertical double-column was provided for each combination of two intervals used in the exercises. For the exercises in the first half of the training, a horizontal space was provided for each appearance of this combination in each exercise. For exercises in the second half of the training, a horizontal space was provided for the one appearance of this combination with each of the four possible rhythms in each exercise. For each item and response, there was an appropriate space for that particular combination of intervals and rhythm pattern.

The information was further compiled with one chart for each mode of training indicating frequency and types of errors.
